University Roll No: 1250258143

Descriptive Analytics Report: Order Trends, App Performance, Customer Experience, Demand and Delivery Workload of Online Food Delivery Apps

Data scope: 6 months, 24 app-month records, covering Swiggy, Zomato, EatSure and Domino's from January–June 2026.

The dataset is synthetic and created for academic demonstration; it is not real company or market-share data.

Keywords: Online Food Delivery Analytics, Data Cleaning, KPI Dashboard, Descriptive Analytics, Order Volume, Revenue, Average Order Value, Delivery Time, Customer Rating, Cancellation Rate, Repeat Customer Rate, App Demand, Delivery Workload, Data Visualization, Data-Driven Decision Making, Excel Reporting.

1. Objective

This report builds a descriptive analytics layer on top of month-by-month data for four online food delivery apps (Swiggy, Zomato, EatSure and Domino's) from January to June 2026. It looks at order volume, revenue, customer experience, app demand, rider capacity and workload. The report is organised around the eight questions below, and the section that answers each one is shown in brackets.

- Which app recorded the highest order volume in the most recent month, June 2026? (Section 4)
- How did total monthly orders change between January and June 2026? (Section 3)
- How do the apps compare on delivery time, customer rating and cancellation rate, and where does performance look weakest? (Sections 4 and 5)
- Why should average order value be read app by app instead of as one pooled figure? (Section 5)
- How are orders and revenue shared across the four apps over the six months? (Sections 6 and 7)
- How many orders does each active rider handle, and which apps reach the Heavy workload tier? (Section 8)
- What do demand and rider capacity together mean for capacity planning? (Sections 6 and 8)
- What would need to change in the pipeline to repeat this analysis over a full year or an order-level dataset? (Sections 2 and 12)

The questions come first because every KPI and chart later in the report was chosen to answer one of them. The report moves from raw order records to descriptive findings, then to workload signals, and finally to what a predictive stage would need.

2. How This Would Work at Real Scale

At real scale, the first challenge is building the data pipeline, well before any advanced analytics. A large food delivery platform can generate millions of order, payment, restaurant and delivery events, so the work is split into ingestion, processing, storage, aggregation and dashboard serving.

Layer	Purpose	Tool / approach
Ingestion	Capture order, restaurant, payment and delivery events	ChatGpt
Stream processing	Convert raw events into order and delivery aggregates	Claude
Storage	Keep raw data for audit plus cleaned analytical tables	Google
Batch aggregation	Daily and monthly summaries, KPIs and reconciliation	Excel for this sample dataset
Serving / BI	Refresh dashboards after each reporting period	ChatGpt

Why this matters for analytics: raw order events have to be cleaned and standardised before any KPI is calculated. This project uses app-month aggregates to show the reporting structure without needing millions of individual records.

Descriptive to predictive: a clean and repeatable pipeline matters before any forecasting is attempted. If orders, revenue, delivery times or cancellations are recorded inconsistently, a predictive model will learn unreliable patterns, so data cleaning and aggregation come first.

3. Month-by-Month Order Trend

The dataset holds 24 app-month records across the four apps, with 16,895 orders and ₹3,518,250 in revenue over the six months. Revenue is reported here as a six-month total, while Figure 1 shows the month-by-month movement in orders.

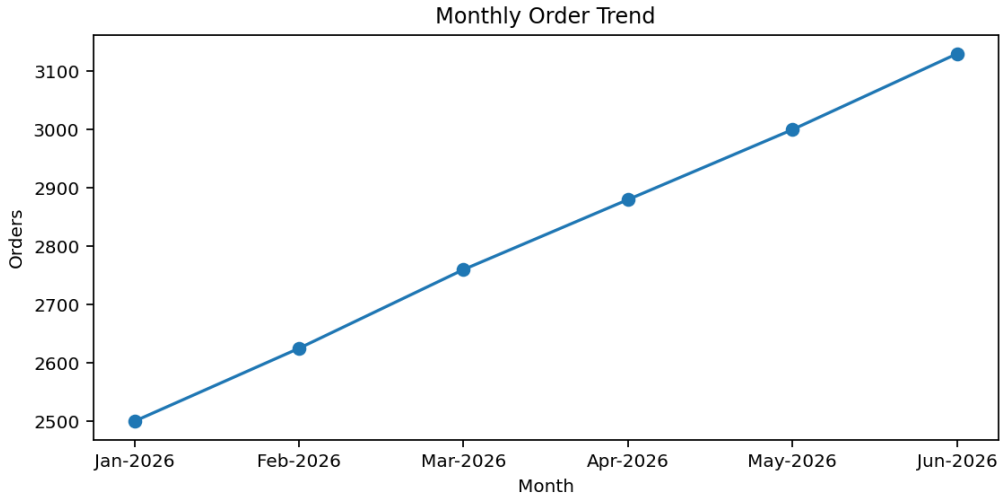

Figure 1. Monthly order trend, January to June 2026.

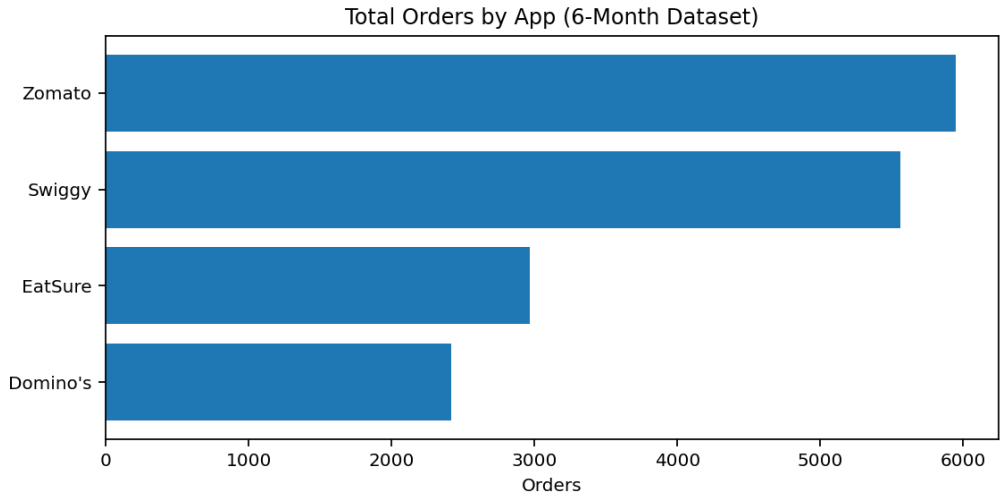

Figure 2. Total orders by app across January–June 2026.

Monthly orders rise every month, from 2,500 in January to 3,130 in June. That is an increase of 630 orders, or 25.2%, and each monthly gain stays between 120 and 135 orders, so growth is steady rather than a one-off jump. Figure 2 shows where the six-month volume comes from: Zomato (5,950 orders) and Swiggy (5,560) lead, followed by EatSure (2,970) and Domino's (2,415).

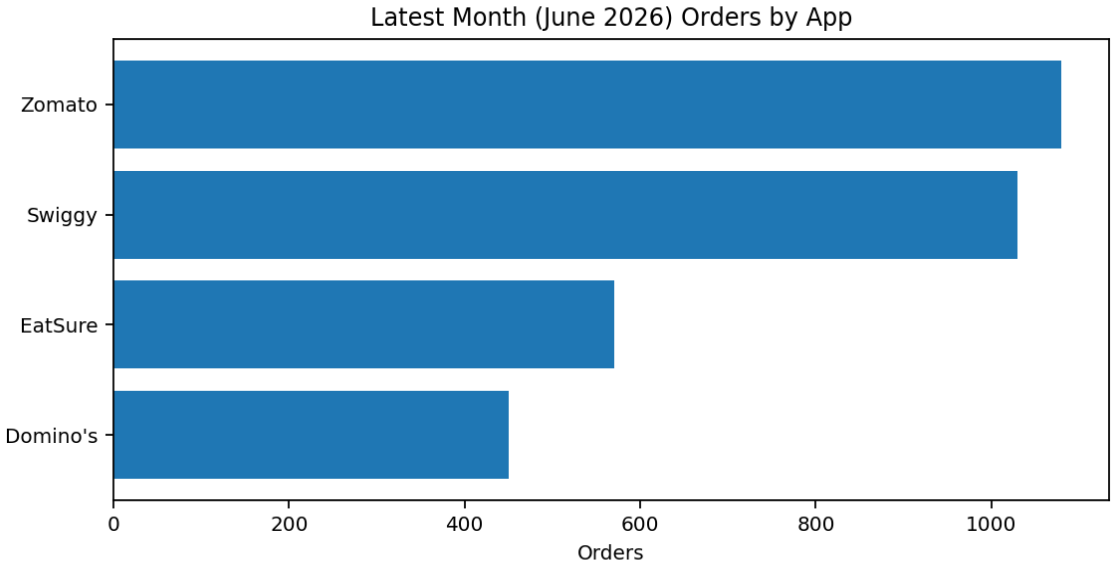

These totals describe what happened. With a longer history, the same trend together with seasonality and promotions could be used to estimate future demand.

4. App Comparison for the Most Recent Month

The table below compares the four apps for June 2026, ranked by number of orders.

App	Orders	Revenue	Delivery (min)	Rating	Cancellation
Zomato	1,080	₹226,800	29.2	4.3	4.9%
Swiggy	1,030	₹216,300	29.8	4.3	4.6%
EatSure	570	₹114,000	32.1	4.4	3.9%
Domino's	450	₹94,500	31.7	4.4	3.5%

Figure 3. Orders by app in the latest month (June 2026).

Zomato recorded the highest order volume in June with 1,080 orders, followed closely by Swiggy with 1,030. Together they account for 67.4% of the month's 3,130 orders. Revenue is kept as its own column because high order volume and high value per order are not the same thing.

When demand sits with only a few apps, planning depends heavily on how much capacity those apps have. This is treated here as a planning signal, not as a claim about real market share.

5. Delivery Time, Rating and Order Value

Across all 24 app-month records the pooled weighted averages are ₹208.24 for order value, 31.1 minutes for delivery time and 4.22 out of 5 for customer rating. These work as baselines, but the differences between apps are more useful.

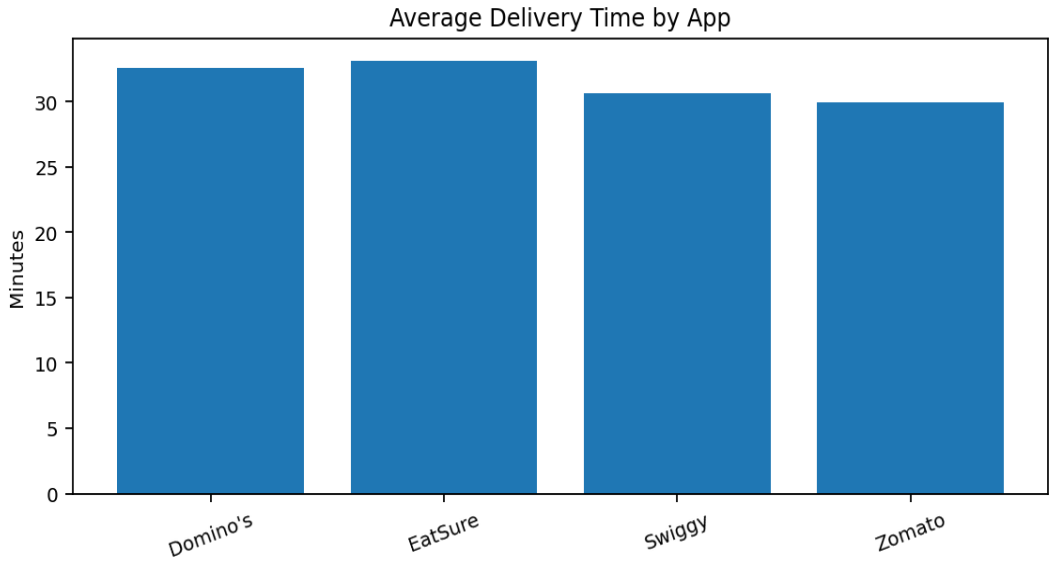

Figure 4. Average delivery time by app (six-month average).

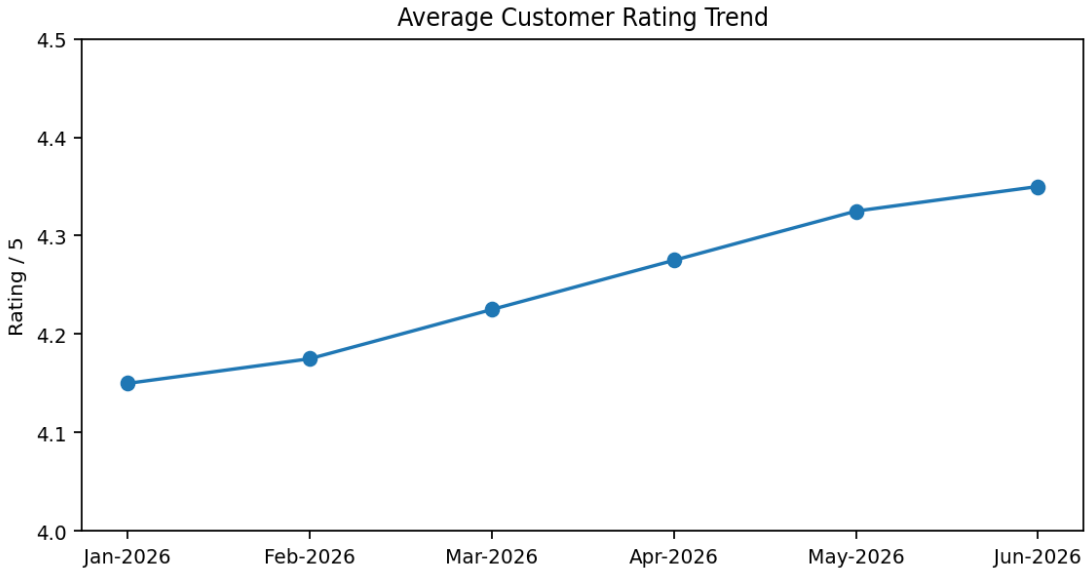

Figure 5. Average customer rating by month, January to June 2026.

Delivery time and rating. Zomato (30.0 min) and Swiggy (30.6 min) are the fastest apps over the six months, while Domino's (32.6 min) and EatSure (33.1 min) are slower. Figure 5 shows ratings improving every month, from about 4.15 in January to 4.35 in June.

Where performance is slipping. In June, Zomato has the highest cancellation rate (4.9%) and Swiggy is next (4.6%), even though they are the fastest apps and handle the most orders. EatSure has the slowest June delivery time (32.1 min), and Domino's has the lowest cancellation rate (3.5%).

Order value. The pooled figure of ₹208.24 hides differences between apps. Dividing revenue by orders gives ₹210 for Zomato, Swiggy and Domino's and ₹200 for EatSure, so an EatSure order is worth about 5% less. The pooled number is simply a blend of these values and moves whenever order share shifts from one app to another.

- **Early warning:** delivery time or cancellation rate that rises for several months in a row may point to an operational pressure point.

- **Customer experience:** a stable or improving rating together with shorter delivery time is good evidence of consistent service.

These month-to-month indicators could become features in a forecasting model, which would compare each app's recent performance with its own baseline and flag likely deterioration.

6. App Demand and Rider Capacity

The table gives the six-month orders, revenue and average service indicators for each app.

App	Orders	Revenue	Avg Delivery	Rating	Repeat Rate
Zomato	5,950	₹1,249,500	30.0	4.15	42.5%
Swiggy	5,560	₹1,167,600	30.6	4.20	40.5%
EatSure	2,970	₹594,000	33.1	4.30	36.5%
Domino's	2,415	₹507,150	32.6	4.35	38.5%

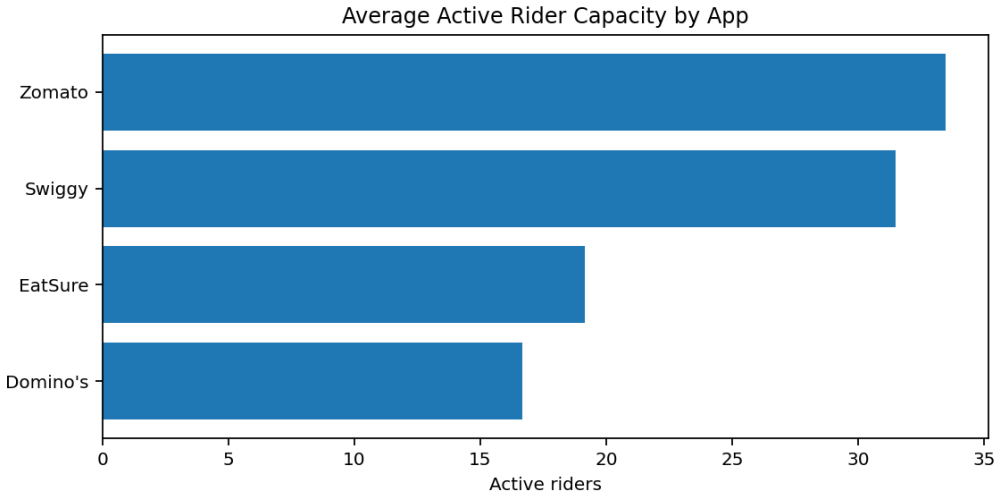

Figure 6. Average active rider capacity by app.

Zomato and Swiggy generate 11,510 of the 16,895 orders (68.1%) and also have the largest rider pools, at roughly 31 to 34 active riders each in Figure 6 against about 17 to 19 for EatSure and Domino's. Zomato has the best repeat-customer rate (42.5%) even though its six-month rating (4.15) is the lowest of the four, so repeat ordering does not follow rating one-to-one in this data.

- **Capacity planning:** high-demand months affect rider scheduling and delivery-zone planning.
- **Customer retention:** the repeat-customer rate shows whether demand is recurring or mainly promotion-driven.
- **Revenue planning:** revenue should be watched alongside orders, because average order value changes the financial impact of the same demand.

With a larger dataset, order growth, rider capacity, weather, day of week, promotions and restaurant availability could be combined to estimate future delivery demand.

7. Pie-Chart Analysis

The pie charts add a part-to-whole view to the line and bar charts above. They use the same six-month dataset.

7.1 Six-Month Order Share by App

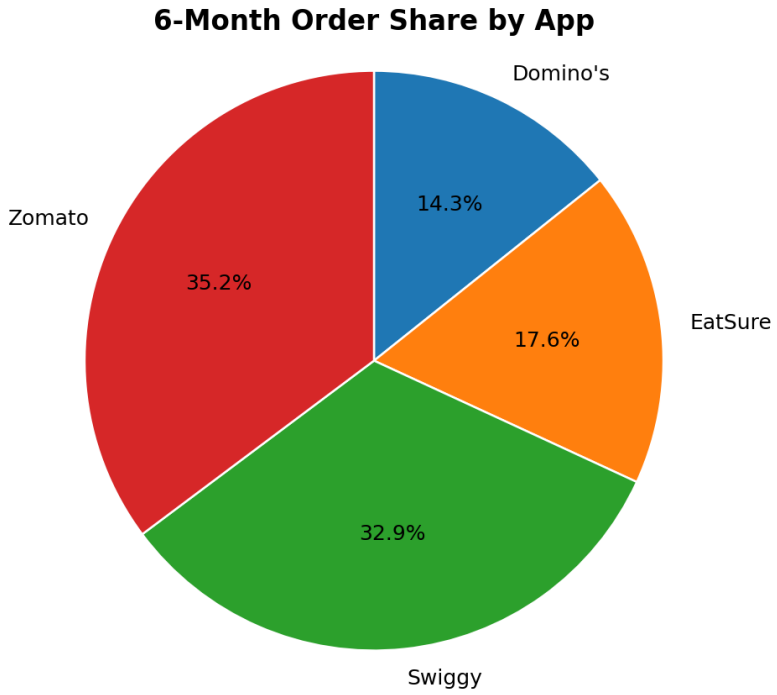

Figure 7. Six-month order share by app.

Zomato accounts for 35.2% of orders and Swiggy for 32.9%, together 68.1%. EatSure (17.6%) and Domino's (14.3%) share the rest.

7.2 Six-Month Revenue Share by App

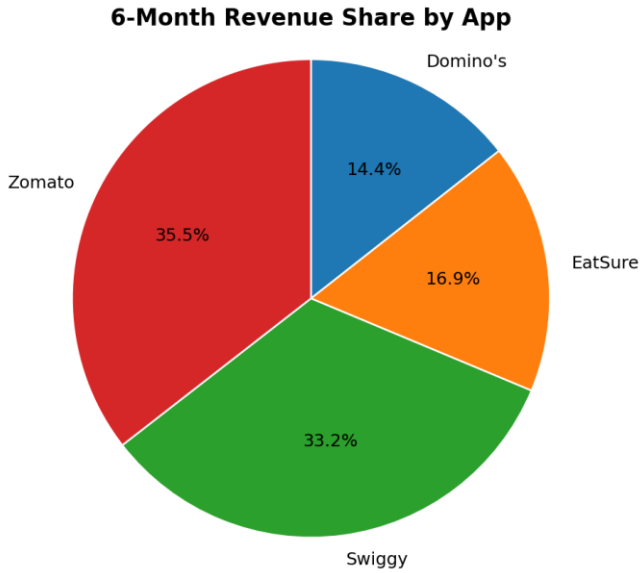

Figure 8. Six-month revenue share by app.

Revenue shares are close to order shares: Zomato 35.5%, Swiggy 33.2%, EatSure 16.9% and Domino's 14.4%. EatSure's revenue share is a little lower than its order share because its average order value (₹200) is below the ₹210 of the other apps.

7.3 June 2026 Order Share by App

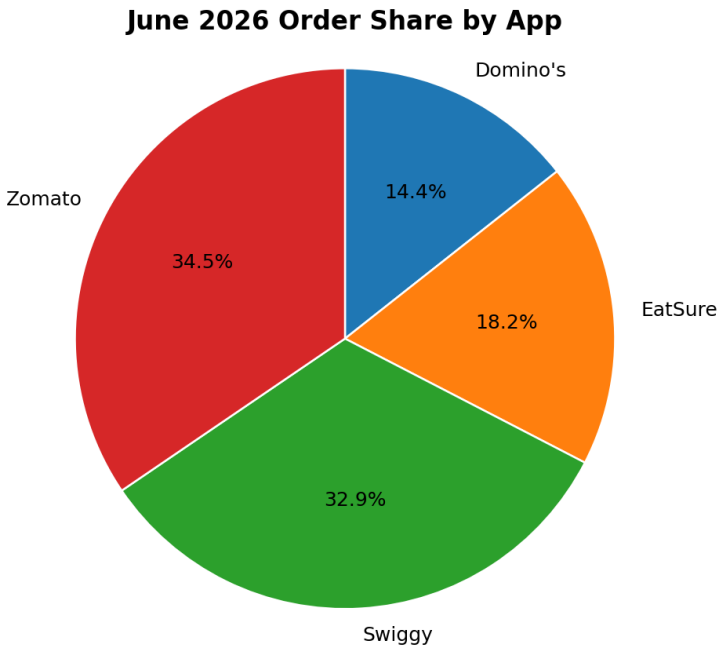

Figure 9. June 2026 order share by app.

In June the split is Zomato 34.5%, Swiggy 32.9%, EatSure 18.2% and Domino's 14.4%. Compared with the six-month picture, EatSure's share has risen slightly and Zomato's has slipped slightly.

7.4 Completed vs Cancelled Orders

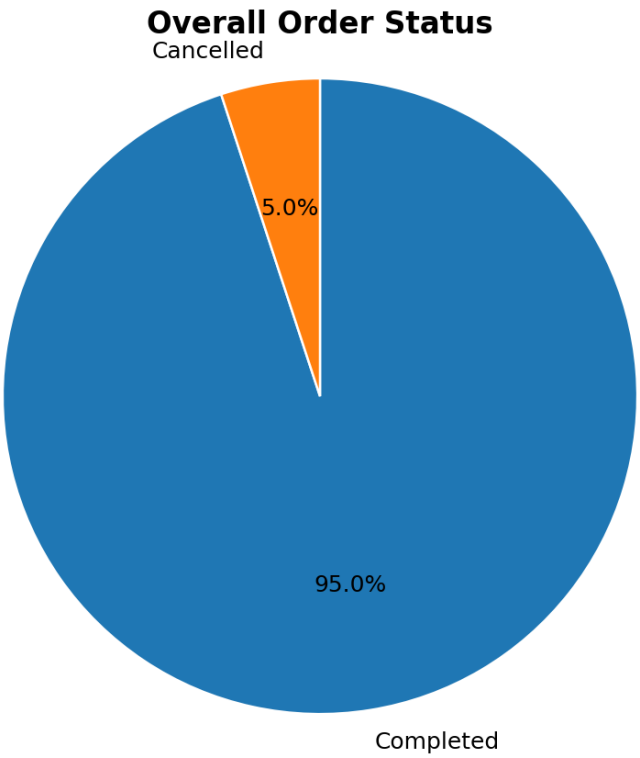

Figure 10. Completed and cancelled orders, six-month total.

The weighted cancellation rate across the dataset is about 4.95%, so roughly 95.05% of orders were completed. The cancelled slice is small, but it is tracked as a separate service-quality KPI.

8. Delivery Workload Status

Delivery workload is divided into three tiers using orders handled per active rider: Light (25 or fewer orders per rider), Moderate (more than 25 up to 29) and Heavy (more than 29). The Heavy tier is treated as a watch zone for operations, not as an automatic sign of rider stress.

App	Month	Orders	Active Riders	Orders/Rider	Tier
Zomato	Feb-2026	940	32	29.4	Heavy
Swiggy	Mar-2026	910	31	29.4	Heavy

The table lists the app-months that reach the Heavy tier: Zomato in February and Swiggy in March, both at 29.4 orders per rider. These are also the two apps with the largest rider pools (Figure 6) and the highest June cancellation rates, so they are the ones to keep an eye on.

A high orders-per-rider figure only says that average rider capacity is carrying more demand. It does not prove fatigue, service failure or unsafe working conditions, so workload should be checked against delivery time, cancellation rate and rider availability.

Operational analytics could later combine orders per rider with delivery-time trends, order density, shift duration and past capacity to estimate where extra riders may be needed.

9. Key Findings

- **Orders grow steadily.** Monthly orders rise from 2,500 in January to 3,130 in June, a 25.2% increase within this synthetic dataset.
- **Demand is concentrated in two apps.** Zomato records 5,950 orders and Swiggy 5,560 over six months, together 68.1% of the total. This is concentration within the dataset, not a real-world market-share estimate.
- **Customer experience improves gradually.** The weighted average delivery time is 31.1 minutes and the weighted average rating is 4.22/5, with ratings rising every month.
- **Cancellation is a separate KPI.** The weighted cancellation rate is 4.95%, and in June the busiest apps (Zomato and Swiggy) have the highest rates, so order volume alone does not describe the customer experience.
- **Workload needs context.** Zomato and Swiggy reach the Heavy tier at 29.4 orders per rider. This is a capacity-planning signal that should be read alongside delivery time, cancellations and rider availability.
- **The dataset is small on purpose.** 24 app-month records are enough to show the reporting structure, but a full order-level history would be needed for stronger predictive modelling.

No single number should be read in isolation: order volume needs revenue context, delivery time needs customer-experience context, and workload needs capacity context.

10. Key Concepts

10.1 KPI Dashboard

A KPI dashboard is a compact visual summary of the measures that matter most for a decision. The main KPIs in this project are orders, revenue, average order value, delivery time, rating, cancellation rate, repeat-customer rate and orders per rider. The dashboard layer reduces many records to a small set of indicators.

Application in this project: the KPI summary in Section 11 and the descriptive sections turn the raw app-month records into a compact reporting layer.

10.2 Food Delivery Analytics

Food delivery analytics is the use of statistical and data-driven methods on restaurant ordering and last-mile delivery. It supports demand planning, restaurant operations, customer retention, delivery capacity and service monitoring. This report covers only the descriptive stage.

Why it matters: it links a small academic dataset to the way a larger analytics pipeline would work in practice.

11. Summary of Key Metrics

Metric	Value
Total app-month records	24
Total orders	16,895
Total revenue	₹3,518,250
Weighted average order value	₹208.24
Weighted average delivery time	31.11 min
Weighted average customer rating	4.22 / 5
Weighted cancellation rate	4.95%
Weighted repeat-customer rate	40.22%
Apps tracked	4
Months tracked	6

These KPIs are the anchor of the report. They reduce the dataset to a few numbers that can be tracked after every reporting period, and they only become useful when compared across time, apps, demand and capacity.

With more history, the same KPIs could serve as baseline variables for a forecasting pipeline, which would learn expected ranges and flag unusual changes instead of just displaying the current value.

12. Next Steps: From Descriptive to Predictive

The current report answers “what happened?” The next layer asks “what is likely to happen next?” Three natural directions are demand forecasting, anomaly detection and customer behaviour modelling.

Current descriptive layer	Predictive next layer	Expected output
Recent order trend	Demand forecasting	Expected order range for the next period
Sudden delivery/cancellation movement	Anomaly detection	Potential unusual-operation signal
Customer and app history	Retention / repeat-order modelling	Likelihood of repeat ordering
App + rider capacity history	Capacity forecasting	Expected rider-capacity requirement

1. Demand forecasting: use recent orders, day of week, seasonality, promotions, app and location variables to estimate future order demand.

2. Anomaly detection: spot sudden changes from an app's normal delivery time, cancellation rate or rating. An anomaly is a signal to investigate, not a confirmed cause.

3. Customer behaviour modelling: use repeat-order history, order frequency, average order value and app interaction data to see which customers are more likely to return.

Overall, the report moves from data cleaning to KPI measurement, descriptive charts, capacity indicators, predictive features and finally forecasting. The 24-record synthetic dataset shows the structure, and a full order-level dataset would make the predictive stage much stronger.

Appendix: Dataset Structure

The accompanying Excel workbook contains the same data used for the calculations and charts in this report. The dataset is synthetic and was built for academic use.

Field	Meaning
Month	Reporting month from January to June 2026
App	Food delivery app/service represented in the dataset
Orders	Number of orders recorded for the app-month
Revenue_INR	Synthetic revenue value in Indian rupees
Avg_Order_Value_INR	Revenue divided by orders for the app-month
Avg_Delivery_Min	Average delivery time in minutes
Avg_Rating	Average customer rating on a 5-point scale
Cancellation_Rate_pct	Percentage of orders cancelled
Active_Riders	Synthetic average active rider count
Discount_Rate_pct	Synthetic share of orders receiving a discount
Repeat_Customer_Rate_pct	Synthetic share of orders from repeat customers
Orders_per_Rider	Orders divided by active riders
Workload_Tier	Light, Moderate or Heavy based on orders per rider

Academic-use note: the figures are created to demonstrate descriptive analytics, Excel reporting and chart construction. They should not be presented as actual market-share, revenue or service-performance statistics for the named companies.

End of Report.
